MESSAGE

Goat Plague or Peste des petits ruminants (PPR), is an acute viral disease of small ruminants, causing several clinical signs like high fever, oculo-nasal discharges, respiratory distress and diarrhoea and mass mortality in unvaccinated population. Small ruminants are very important for livelihood of the rural farmers. Around 11 million tonnes of meat and 22 million tonnes of milk contributing to 78 percent total annual global production comes from small ruminants of Africa and Asia. PPR is prevalent in around 70 countries in Africa, the Middle East and Asia, and posing threat to more than 1.7 billion of total 2.1 billion sheep and goat population, and also livelihood of more than 330 m people in these regions. FAO and OIE have developed a strategic plan for eradication of PPR by 2030. India has sufficient capacity to control the disease with indigenously developed diagnostics, prophylactics and well trained manpower. The scientific community has developed confidence after successful eradication of rinderpest, a similar disease of livestock animals. Department of Animal Husbandry and Dairying, Govt. of India initiated the national control programme for PPR (PPR-CP) using its own resources based on the available epidemiological data, indigenously developed diagnostics, and vaccines to mitigate the disease burden even before the global framework was developed. PPR control and eradication depends mainly on rapid and accurate diagnosis or surveillance/monitoring and implementation of the prompt vaccination programme. Under National PPR Control and Eradication Strategic Plan of the country, it is envisaged to control the disease by vaccination, evaluation of its efficacy by sero-monitoring and sero-surveillance. Considering the vast population of 148.88 m goats and 74.26 m sheep in India, while studying vaccination efficacy, sampling plan is very important for systematic collection of representative samples and thereafter testing in laboratories for monitoring & surveillance of PPRV antibodies. The sampling plan provided in this handbook has been prepared following OIE guidelines and it will provide guidance for collection of representative samples from different parts of the country to be tested for PPR vaccine or PPRV infection-induced antibodies under PPR-CP.

I compliment the Director and Scientists of ICAR-NIVEDI for undertaking the initiative to prepare this beneficial handbook to be used in the PPR control programme in India.

FOREWORD

Peste des petits ruminants (PPR) is an acute viral disease of small ruminants characterized by high fever (pyrexia), discharges from eyes and nasal orifices, necrotizing and erosive stomatitis, gastroenteritis, diarrhoea and bronchopneumonia, resulting in high mortality in susceptible unvaccinated flock. The disease is enzootic in India and causes an annual loss of INR.1611 crore at an annual disease incidence of 10%. India has sufficient skill, vaccine and diagnostics to control the disease. After successful eradication of rinderpest, high level of confidence exists among the scientific community to control and eradicate PPR also. The FAO and OIE have developed a global strategic plan for eradication of PPR by 2030. Govt. of India has taken initiative to control PPR by vaccination of all susceptible sheep and goat population for which central financial assistance is provided. Department of Animal Husbandry and Dairying, Government of India initiated a vaccination programme during 2010-11 in a few states and later extended to all the states in the Country, which showed progressive control of the disease and drastic decline in outbreaks. The national control programme envisaged to control the disease by vaccinations and evaluation of its efficacy by sero-monitoring and surveillance in the National PPR Control and Eradication Strategic Plan. Considering the huge resource of 223.14 million small ruminant population in India, it is difficult to sample all animals, while studying vaccination efficacy or for surveillance. The sampling plan provided in this handbook will be very useful for collection of samples to undertake sero-surveillance or post vaccinal sero-monitoring in this vast country.

I compliment the Director and Scientists of ICAR-NIVEDI for taking the initiative to prepare this handbook entitled "Sampling Plan for Serosurveillance & Seromonitoring of Peste des Petits Ruminants (PPR)" to be used in the PPR control programme in India.

Sampling plan

**Serosurveillance & monitoring of
Peste des Petits Ruminants (PPR)**

The sampling plan for serosurveillance and seromonitoring of Peste des Petits Ruminants (PPR) under National PPR Control Programme (PPR-CP) has been prepared as per OIE/FAO-Global Control and Eradication Strategy for PPR guidelines (FAO-OIE,2015).

Abstract

Peste des petits ruminants (PPR), otherwise known as ‘Small ruminant plague’ or ‘Goat plague’, is an acute, highly contagious, World Organisation for Animal Health (OIE) notifiable and transboundary viral disease of sheep and goats. PPR is caused by the small ruminant morbillivirus (SRMV), formerly known as peste des petits ruminants virus (PPRV). Clinically, the disease is characterized by high fever (pyrexia), discharges from eyes and nasal orifices, necrotizing and erosive stomatitis, gastroenteritis, diarrhoea, and bronchopneumonia. The disease poses a substantial threat to the small ruminants’ sector and it significantly impacts the food security and national economy of the country. In enzootic India, the disease causes major constraints in augmenting the productivity of sheep and goats with an annual estimated financial loss of Indian rupees (INR) ~16118 million. After eradication of rinderpest, a global consensus on PPR Global Control and Eradication Strategy (GCES) has been reached on the need to control and eradicate the disease by 2030 due to its economic significance. The recent success with the rinderpest eradication programme (NPRE) in the country has provided the confidence and impetus to launch a similar programme for PPR. India initiated the national control programme for PPR (PPR-CP) using its resources based on the available epidemiological data, indigenously developed robust diagnostics, and vaccines to mitigate the disease burden even before the global framework were developed. PPR control and eradication depends mainly on rapid and accurate diagnosis or surveillance/monitoring and implementation of the prompt vaccination programme.

Department of Animal Husbandry and Dairying, Government of India has taken the initiative to control PPR by vaccinations and evaluation of its efficacy by sero- monitoring and surveillance in the National PPR Control and Eradication Strategic Plan 2025. Considering the huge livestock resources in India, while studying vaccination efficacy, sampling plan is very important for systematic collection of representative samples and thereafter testing in

laboratories for monitoring & surveillance of PPRV antibodies in the small ruminants population. The sampling plan provided in this handbook following OIE guideline for the collection of samples from different parts of the country to be tested for PPR vaccine or PPRV infection-induced antibodies response under PPR-CP and to be used in the PPR control programme in India.

A cross-sectional seroprevalence study to be conducted to ascertain the prevalence status of PPR virus antibodies in small ruminants population in the epidemiological units (epi-units) of different states in India, for serosurveillance or seromonioring of PPR in India. The initial hypothesis is that PPR antibodies are homogeneous or independent in the populations of the epi-units in the study region. The rural societies live in villages consisting of clusters of households that follow similar animal husbandry and socio-economic activities. Hence, the village is considered a distinct epi-unit in this study as described earlier. Accordingly, a list of villages in various blocks/ tehsils in different districts in the state and their sheep and goat populations as per the 20th Livestock census, 2019 in each of the state was prepared and to have a sizeable population, the villages (epi-units) having more than 100 or 200 or 500 sheep and goats (with inclusion and exclusion criteria, as the case may for each state) were shortlisted for the sampling frame.

The sample size was determined as per Cochran, (Cochran 1963) formula by using epitool. For the calculations of the Sample cluster unit (epi-unit), the indigenous PPR Competitive ELISA diagnostic sensitivity (92.4%) and diagnostic specificity (98.4 %), was considered, along with 95% Confidence Interval (CI) and 5% or 10% standard error. To calculate the sample size of epi-units with a specified level of confidence (CI) and precision, assuming an unknown large population of epi-units, the formula $n = (Z^2 \times P(1 - P))/e^2$; Z = Value from the normal distribution; P = Expected proportion of epi-units protected; e= Desired precision is used. where n is the sample size for the state, Z is the 95% confidence level (standard normal value of 1.96), p is the prevalence, which is to be taken as 30 % for pre-vaccination sero-monitoring and 70% will be taken as immune population/ herd immunity at field level for post-vaccination sero-monitoring. ‘e’ is the precision of sample size estimate and is normally set at 5% (0.05) or 10 % (0.10), as is the acceptable sampling error, as per OIE/FAO-Global Control and Eradication for PPR (GCEP) guidelines (OIE and FAO 2015). Based on these input parameters, the total number of sample size (Epi-units) within a study area were estimated for PPR sero-monitoring /surveillance in a particular state. Further, to account for variation in the sensitivity/specificity of diagnostic test/assay, the formula has been

modified, and accordingly, the sample size estimation for identifying the number of clusters or villages or epi-units to be carried out was done by epi-calculator. Using the above formulae with the following inputs, viz., the Unit level design prevalence 30 %; cluster-level design prevalence (3%) and target cluster sensitivity (92.4 %), the sensitivity of the test /assay to be employed (92.4 %) and with target system sensitivity of 95 % confidence level, **the estimated sample size - Epi-unit** clusters to be sampled for pre-vaccination / post-vaccination / population immunity assessments was minimum of **108 (Villages or Epi-units)/study areas (state or UT)**.

For PPR sero-monitoring /surveillance, a multistage random sampling technique to be employed to collect serum samples from sheep and goat rearing household/ flocks as per OIE/FAO guidelines. The Multi-stage random sampling technique with a fixed level or the required number of clusters units / epi-units regarding small ruminant population where PVE is implemented to be carried out with random allocation.

Considering the huge small ruminants (~200 million) resources in India, in the first stage, the study area purposefully selected (as the state), where PVE needs to be evaluated. In the second stage, the districts where the vaccination programme is implemented in a particular state need to be selected. In the third stage, in each of the districts, villages as an epidemiological unit (epi-unit) to be selected randomly. Randomization of villages was done based on the in-house NIVEDI developed software epi-calculator. Before randomization, the trimming of the sampling frame (source of villages from which samples to be drawn) is employed for 500 animals per village as an inclusion criterion. However, in some of the villages with less sheep and goats population, the inclusion criteria will be 100 or 200 or 300 animals per village, as the case may be for each state. The required number of epi-units needs to be calculated and allocated randomly among the districts.

In the fourth stage, the flocks or households to be surveyed in each of the selected villages or epi-unit. The selection of flock/household within the village will be done based on systematic random sampling with prior preparation of sampling frame (flocks) having a minimum of 20 animals. In the next stage in each of the selected villages, the number of secondary units (animals) were calculated by the hypergeometric distribution as per GCES guidelines by considering an animal unit-level prevalence of 30% (OIE FAO 2015b) in small ruminants. In each epi-unit/village, sera to be collected randomly from 3 or 4 flocks or households. The maximum level of 9 to 10 samples to be collected was determined based on the small ruminants populations in each epi-unit. In the epi-unit, where only either sheep or

goats were present, a maximum of 9-10 samples of either species to be collected. Maximum of 3 animals per each eligible age group or stratum (age = between 6-12 months, one to 2 years and > 2 years) or 3 animals in 6-12 months age group and 6 animals in more than one-year age group, in each flock/household, with a total of 9 or 10 samples from each selected flock to be collected. Thus, a maximum of **3240 secondary animal units to be collected for** serosurveillance of the PPR in each State/UT of India was established using the epi-calculator https://www.nivedi.res.in/Nadres_v2/Erical/stratified/random_sampling.php) for pre-vaccination or population immunity assessments. For post-vaccination assessment, a **total of maximum 9 to 10 samples from each of the selected villages / epi-unit to be collected randomly from 6 to 12 months aged animals only**, from three or four selected flocks, with earlier described population and species proportion ratios in the **provided sampling plan for each State/UT as such directly**. Thus, a maximum of **1080 secondary animal units to be collected for** seromonitoring of the PPR in each State/UT of India.

The collected sera were labeled and transported in an ice-cool shipment container to the laboratory and samples were stored at -20 °C until further testing for PPRV antibodies. The sero-surveillance and seromonitoring of the PPR in India will be carried out by using an approved PPR C-ELISA kit.

Sampling plan

for Serosurveillance & monitoring of Peste des Petits Ruminants (PPR)

Sampling plan for Serosurveillance & Seromonitoring of Peste des Petits Ruminants

Introduction

Peste des petits ruminants (PPR), otherwise known as '**Small ruminant plague**' or '**Goat Plague**', is an acute, highly contagious, and transboundary viral disease of sheep and goats. It is caused by the small ruminant morbillivirus (SRMV), formerly known as PPR virus (PPRV), a member of the genus *Morbillivirus* of the family *Paramyxoviridae*. Clinically, the disease is characterized by high fever (pyrexia), oculonasal discharges, necrotizing and erosive stomatitis, gastroenteritis, diarrhoea, and bronchopneumonia, followed by either death of the animal or recovery from the disease. PPR is a major constraint and affects the productivity of small ruminant and it is considered endemic in Africa, in Arabian Peninsula, East-middle east, central, and South East Asia. The disease is widespread and significantly impacts the economy and food security of the endemic countries. Following the worldwide eradication of Rinderpest in 2011, a global consensus was reached on the need to eradicate PPR due to its economic significance.

Further, a PPR Global Control and Eradication Strategy (GCES) was accepted during an international conference on PPR, held in Abidjan, Côte d'Ivoire, in April 2015, with the vision of a PPR-free world by 2030. During, 2016, an initial PPR Global Eradication Programme (PPRGEP) for 2017-2021, was launched by the FAO and OIE to put the GCES into action. European Commissioner for International Cooperation and Development, FAO, and OIE jointly launched an international strategic plan for control and eradication of PPR by 2030 intending to gather all stakeholders behind the PPR-GEP and mobilize the additional support required for the eradication of the disease by 2030. In India to control PPR, focused vaccination was practiced in outbreak places since 2002 and programme mode in some states since 2010 -11 even before the global framework was developed. As of now, the disease has been brought under control in some states of India and the occurrence and severity have been progressively and substantially declined in areas under vaccination. PPR control and eradication depends mainly on rapid and accurate diagnosis or surveillance/monitoring and implementation of the prompt vaccination programme. The recent success with the rinderpest

eradication programme (NPRE) in the country, has provided the confidence and impetus to launch a similar programme for PPR.

Sampling Plan

The term “sample” may either mean a specimen (animal, blood sample, and others) or, used in the statistical sense, a sub-collection or subset of units. The aim, in general, is collection of random, representative and independent samples from the study population, as it is difficult to collect materials required for disease monitoring /surveillance from all the animals in a population. Sampling plan/designs vary depending on the problems to be addressed to the study. General principles of PPR serological surveys are to evaluate vaccination effectiveness or Post Vaccination Evaluation (PVE) tool attempts to answer the following points/hypothesis.

- ✓ To establish the baseline level of epi-units that have been exposed to the PPRV before vaccination in the target population (**Prevaccination assessment**).
- ✓ To evaluate vaccination effectiveness by estimating the number of epi-units that demonstrate appropriate seroconversion after each round of vaccination (**Post-vaccination effectiveness**).
- ✓ To evaluate population immunity (number of epi-unit protected) at a given time and overtime after several vaccination campaigns by comparison with the results of the baseline survey (**Population Immunity assessment**).
- ✓ To determine age strata (group), which have been protected for PPR.

Target Population:

It is defined as all susceptible small ruminants at risk of PPR in a particular location.

Study population:

It is defined as epidemiological units (epi-units)/ villages included in the vaccination programme. Animals in the epi-units can be stratified by different age groups /strata. Below 6 months; 6-12 months, 12-24 months, and > 2 years.

Below the 6-month group is excluded from the post-vaccination evaluation, like 0-3 months age group during the post-vaccination survey will remain as unvaccinated animals, as recommended age of vaccination is either at 3 months or 4 months old.

Using three age groups more precise information will be assessed on the particular strengths or weakness of the vaccination campaigns, as certain age groups might have been favoured by farmers when presenting the animals for vaccination. If, however, the primary objective is the evaluation of the overall protection of epi units without considering differences between all age

groups, two groups will suffice: i.e., one group less than one year (6-12months) and another group >1 year.

Epidemiological unit:

The epi-unit is defined considering that all small ruminants within each unit will have the same chance of being vaccinated and the same risk of being infected (or have specific antibodies against PPR). Generally, in the Indian context, the village is as considered the epi-unit, as the rural societies live in villages consisting of clusters of households that follow similar animal husbandry and socio-economic activities.

Sampling designs

For PPR sero-monitoring /surveillance, a multistage random sampling technique to be employed to collect serum samples from sheep and goat rearing household/ flocks as per OIE/FAO-Global Control and Eradication for PPR (GCEP) guidelines. The Multi-stage random sampling technique with a fixed level or the required number of clusters units / epi-units regarding small ruminant population where PVE is implemented to be carried out with random allocation.

Considering the huge small ruminants resources in India,

in the first stage, the study area purposefully selected (as the state), where PVE needs to be evaluated.

In the second stage, the districts where the vaccination programme is implemented in a particular state need to be selected.

In the third stage, in each of the districts, villages as an epidemiological unit (epi-unit) to be selected randomly. Randomization of villages was done based on the in-house NIVEDI developed software epi-calculator. Before randomization, the trimming of the sampling frame (source of villages from which samples to be drawn) is employed for 500 animals per village as an inclusion criterion. However, in some of the villages with less sheep and goats population, the inclusion criteria will be 100 or 200 or 300 animals per village, as the case may be. The required number of epi-units needs to be calculated and allocated randomly among the districts.

In the fourth stage, the flocks or households to be surveyed in each of the selected villages or epi-unit. The selection of flock/household within the village will be done based on systematic random sampling with prior preparation of sampling frame (flocks) having a minimum of 20 animals.

Sampling method:

The selection of flock in the epi-unit will be done with prior preparation of sampling frame (household/flocks) having a minimum of 20 animals/flock within the village. Within each of the selected villages (epi-unit), sheep and goat flocks are selected by systematic random sampling, if feasible, otherwise, random sampling.

Systematic random sampling

First, as per the algorithm of systematic random sampling, the first sample needs to be selected randomly from the frame and subsequent samples are selected for every $K=N/n$ th flock.

Where, K = sampling ratio for selection of flock

N =Total number of flocks in the selected village

n th -number of flocks selected for the survey (3 or 4) as the case may be.

For examples, in a village or epi-unit, a total of 18 flocks having a minimum of 20 animals in the inclusion criteria, the first flock to be selected as random e.g. 4th flock (farm) if selected, then subsequent selection of flock will be based on the sampling ratio (ie., $6 = 18/3$), hence, 10th and 16th flock need to be selected, subsequently for collection of samples. If in the selected flock/household there are not enough animals, then the closest neighbor is to be selected.

Random sampling

In another way, the algorithm of random sampling, any three or four flocks /household in the epi-unit, as the case may be, need to be selected randomly for the collection of animal samples.

Statistical methods

Sample size (cluster units - Epi-units) calculation:

Appropriate statistical techniques need to be adopted for sample collection for monitoring/surveillance of the PPR vaccination programme. For the calculations of the Sample cluster unit (epi-unit), the indigenous PPR Competitive ELISA diagnostic sensitivity (92.4%) and diagnostic specificity (98.4 %), was considered, along with 95% Confidence Interval (CI) and 5% or 10% standard error. To calculate the sample size of epi-units with a specified level of confidence (CI) and precision, assuming an unknown large population of epi-units, the following formula is used:

$$n = (Z^2 \times P(1 - P))/e^2$$

Z = Value from the normal distribution

P = Expected proportion of epi-units protected

e= Desired precision

where n is the sample size for the state, Z is the 95% confidence level (standard normal value of 1.96), p is the prevalence, which is to be taken as 30 % for pre-vaccination sero-monitoring and 70% will be taken as immune population/ herd immunity at field level for post-vaccination sero-monitoring. ‘e’ is the precision of sample size estimate and is normally set at 5% (0.05) or 10 % (0.10), as is the acceptable sampling error, as per OIE. Based on these input parameters, the total number of sample size (Epi-units) within a study area were estimated for PPR sero-monitoring /surveillance in a particular state.

Further, to account for variation in the sensitivity/specificity of diagnostic test/assay, the formula has been modified, and accordingly, the sample size estimation for identifying the number of clusters or villages or epi-units to be carried out is given below.

$$\text{Number of Clusters/Villages/ Epi-units to be sampled } [n] = \{\log(1-\text{sep.sys})/\log(1-[cp*\text{she}])\}$$

Number of units (animal samples) to be sampled [s] for different cluster sizes for target cluster sensitivity (seh); $[s] = \{(cs/se)^* [1-(1-seh)^{1/(cs*up)}]\}$, where,

up= unit –level design prevalence; cp=cluster-level design prevalence; cs=Cluster size
se=unit/test sensitivity; seh=target cluster sensitivity; sep.sys=Target system sensitivity (confidence interval); n=clusters to be sampled; s=number of units to be sampled. Maximum number of samples to be collected will be (n*s).

Using the above formulae with the following inputs, viz., the Unit level design prevalence 30 %; cluster-level design prevalence (3%) and target cluster sensitivity (92.4 %), the sensitivity of the test /assay to be employed (92.4 %) and with target system sensitivity of 95 % confidence level, **the estimated sample size - Epi-unit clusters to be sampled for pre-vaccination / post-vaccination / population immunity assessments was minimum of 108 (Villages or Epi-units).**

Sample size (Number of units -animal samples) calculation:

To calculate the sample size {Number of units (animal samples)} within an Epi-unit to assess whether the level of seroprevalence is above (or below) a given threshold, reference is made to the hypergeometric distribution using the following formula: $n = [1 - (\alpha)^{1/d}] \cdot [N - (d-1)/2]$. Where, n = required sample size; N = population size; d = expected number of seronegative individuals in the population; α : Error type 1 confidence level expressed as a proportion ($=1-\alpha$) [since it is assumed that the test is 100% specificity, there is no type 2 error]. The hypergeometric distribution was used to estimate the probability of finding one or more

seronegative samples in different sample size scenarios. (employing PPR c-ELISA kit has 98.4% specificity)

If a total number or population of small ruminants in epi-unit are more than 94, then, the sample size (number of units *i.e.*, animal samples) to be 9 (nine) or 10 (ten) for that epi-unit, based on the minimum sample size required to assess at 95% CI, if the prevalence of animals is 30 % (as per GCES guidelines). In this PPR sampling plan, as an inclusion criterion, the trimming of the sampling frame employed was 100 to 500 animals per village / epi-unit, as the case may be. Hence, in each epi-unit, a minimum of nine (9) or ten (10) animals from each eligible age group/stratum, randomly need to be sampled, with a maximum of 27 or 30 small ruminant samples, per epi-units for all three eligible age groups,

In overall, a minimum of 2916 to a maximum of 3240 serum samples (unit animal samples) per study area /state need to be sampled for all three or two eligible age groups to measures of degree of susceptibility in the target small ruminant (sheep and goats) population for vaccination.

Pre-vaccination assessment:

For pre-vaccination serosurvey, within flocks or households, animals are selected by simple random methods. Consider sampling a **maximum of 3 animals per each eligible age group or stratum (age = between 6-12 months, one to 2 years and > 2 years) or 3 animals in 6-12 months age group and 6 animals in more than one-year age group, in each flock/household**, as the case may be, with *a total of 9 samples from each selected flock* to be collected.

Finally, **a total of 27 or 30 samples for each epi-unit** to be collected, from the three or four selected flocks, as the case may be, for example,

If the village has only either goats or sheep population, all the 27 or 30 samples need to be collected from either goats or sheep.

If the village has sheep and goats population, in proportion to small ruminants samples need to be collected as per selected villages in the provided sampling plan.

Post-vaccination effectiveness:

To assess the immune response to vaccination, post-vaccination evaluation (PVE), the second serosurvey to be carried out using the above random designs, **after day 30 to 90th day post 1st vaccination**. It is assumed that at least 50% of vaccinated epi-units, will have at least 70% of the seropositive population. **A total of maximum 9 to 10 samples from each of the selected villages / epi-unit to be collected randomly from 6 to 12 months aged animals**

only, from three selected flocks, with earlier described population and species proportion ratios.

Population Immunity Assessment:

For assessing the immune response to vaccination as proxy or representative for the effectiveness of the vaccination campaign or to gather information on the trend of population immunity over time, the proportion of epi-units with >70% of animals protected within 6-12 months age group, need to be compared to the baseline 6 -12 months age group pre-vaccination results. Therefore, a multi-stage stratified random sampling method will be used as described earlier.

Besides sero-monitoring, to assess the impact of the vaccination programme, various parameters like disease intensity, disease cost, the species, and age groups under different farm husbandry practices need to be documented. The above parameters need to collect prior and post-vaccination implementation by adopting an appropriate sampling procedure to quantify the effectiveness of intervention/vaccination.

For each of the states and union territories of India, these estimated epi-units or clusters with a specified confidence level and precision, in an unknown large sheep and goats population to be used for collecting the maximum number of unit animal samples from each epi-unit for seromonitoring /surveillance of PPR in India.

For example for Karnataka State-sero surveillance/monitoring-Multistage random sampling

Survey Area	Country	India	Remarks
1st stage	State	Karnataka	The study area is purposefully selected as the state
2nd Stage	Districts	All districts	All the districts of the particular state selected
3rd Stage	Villages /Epiunits	108 villages covering all the districts	Before randomization, the trimming of the sampling frame (source of villages from which samples to be drawn) will be employed for 100 or 200 to 500 animals per village as an inclusion criterion. In each of the district, villages as an epidemiological unit (epi-unit) to be selected randomly concerning the size of the population
4th Stage	Household or Flocks	3 or 4 flocks in the villages	Based on the small ruminants population, a maximum of 3 animals per each eligible age group or stratum (age = between 6-12 months, one to 2 years and > 2 years) or 3 animals in 6-12 months age group and 6 animals in more than one-year age group.
Total no. of samples	Minimum samples size = 108 x 27 = 2916 samples or Maximum samples size = 108 x30= 3240 samples per State		
Total samples per year	Pre-vaccination study – 30 samples (10 from 6-12 months old animals and 20 from > 1-year old animals). Post-vaccination-study -10 samples from 6-12 months old age group animals only. 108 villages x 40 total samples = 4320 grand total		

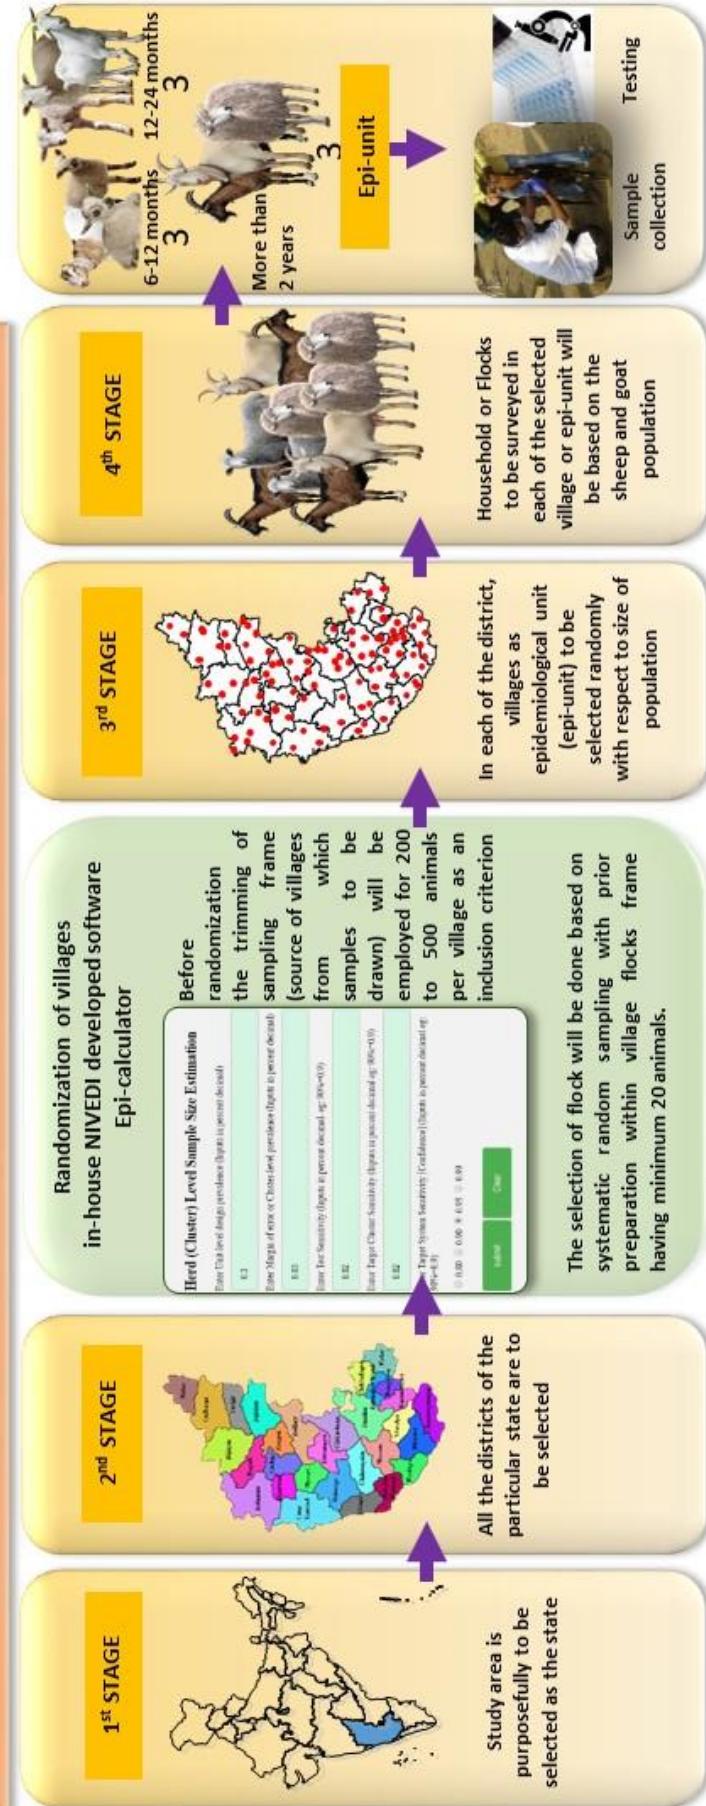

Sampling Design

PPR Sero-Monitoring / Surveillance in India

Multistage stratified random sampling technique

↓ OIE/FAO-GCFS for PPR guidelines

With fixed level of sample cluster unit (Epi-unit), with reference to small ruminant (sheep and goat) population

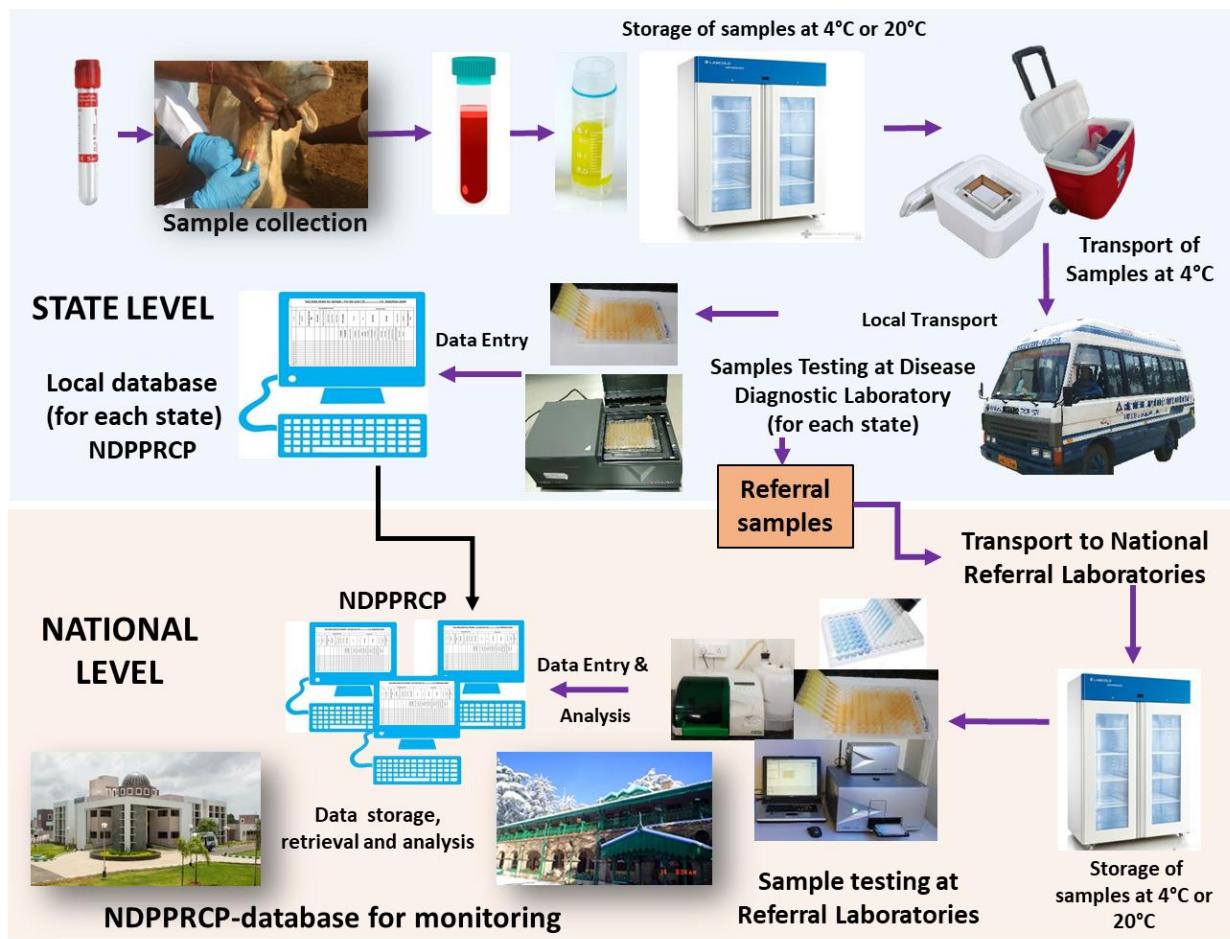

Collection and storage of samples

- Sample collection is done for definitive serological diagnosis/monitoring of PPR.
- Before the collection of blood, make the area of skin surface sterile by using alcohol swabs. Collect blood from animals using sterile vacutainer.

- Collect 5 to 8 ml of blood per animal which can be used for various tests and diagnoses of disease.
- Collected blood samples in vacutainer tubes, to be labeled and label details recorded in each animal's details with the unique ID of the samples. The tubes need to be placed in a cool shipment box with ice packs and transported to the laboratory and upon receipt, samples need to be stored at 4°C until further use.
- For serum, collect the blood in tube coated with sodium silicate vacutainer tubes which favors clot formation and easy separation of serum. The serum should be separated by centrifugation at 2000 rpm for 15 to 20 minutes.
- The serum collected may be used for the serological investigations and it should be stored in two aliquots at -20°C until used and this serum can be used for detection of PPRV antibodies for monitoring.
- The collected samples detail to be entered in the data excel sheet format for uploading in the NDPPRCP web application for subsequent retrieval of data, sharing, and analysis for monitoring and evaluation of the PPR_CP programme.

Transport of samples

- Do not transport material for culture in the needle and syringe. Needle transport is very unsafe because there is always the risk of a needle stick injury, and syringe transport poses a risk because specimens may be expelled during transport, creating a threat to personnel and the environment. Transfer aspirated material to a tight container.
- The sample containers should be properly labeled and identified. The labels like “Clinical Specimen/Blood samples, Fragile and Handle with care” may be specified on the container or the parcel containing the samples.
- The sample container should have details like the nature of the sample, epi-units ID, animal number, place, and date of the collection which is important for easy identification and tracking of samples.
- The samples should be sent with proper sample details in a separate sheet which will help in the testing of the samples for PPR by ELISA.

- The serum samples should be transported on the ice at 4°C to prevent the decomposition of the serum proteins. The samples are to be stored upon arrival if the processing is delayed and usually done using refrigeration.
- The serum can be stored at freezing conditions at 0°C or -20° C for long time storage without decomposition of the serum proteins.

Note:

- ❖ The proper and systematic collection, dispatch, and storage of samples are necessary and given at most care for proper diagnosis/ monitoring /surveillance of animal diseases.
- ❖ The efforts made in diagnosis/monitoring will go waste if proper or representative samples are not collected. Hence, the collection of samples should be given more importance for proper diagnosis/ monitoring of animal diseases

Serum samples from each Epi-unit should contain the following details for sero-monitoring / surveillance purpose under PPR CP programme

Write appropriately or (✓) tick Mark in the relevant columns— Model (Annexure)

For example Epi-unit (ID-598653) in Karnataka State

Note: Samples to be transported to the laboratory in the cold chain at 4° C

Guidelines

The sampling plan for serosurveillance and seromonitoring of Peste des Petits Ruminants (PPR) under National PPR Control Programme (PPR-CP) has been prepared as per OIE/FAO-Global Control and Eradication Strategy for PPR guidelines (FAO-OIE,2015).

Pre-vaccination or population immunity assessment:

For pre-vaccination or population immunity serosurvey, a total of 27 or 30 samples for each epi-unit / village are to be collected, from the three or four randomly selected flocks, as the case may be, for example, If the village has sheep and goats population, samples need to be collected in proportion as provided in the **sampling plan for each State/UT multiply of 3 (three)**. If the village has only either goats or sheep population, all the 27 or 30 samples need to be collected from either goats or sheep. Thus, a maximum of **3240 secondary animal units (animal serum samples)** are to be collected for serosurveillance of the PPR in each State/UT of India by using an approved PPR C-ELISA kit. Within the selected flock or household, animals are selected by simple random method. A maximum of 3 animals per each eligible age group or stratum (age = between 6-12 months, one to 2 years and > 2 years) **or 3 animals in 6-12 months age group and 6 animals in more than one-year age group are recommended in each flock/household**, with a total of 9 or 10 samples from each selected flock are to be collected.

Post-vaccination effectiveness or Assessments

To assess the immune response to vaccination, post-vaccination evaluation (PVE), the second serosurvey to be carried out using the above random designs, **after day 30 to 90th-day post 1st vaccination**. It is assumed that at least 50% of vaccinated epi-units, will have at least 70% of the seropositive population. **A total of maximum 9 to 10 samples from each of the selected villages / epi-unit to be collected randomly from 6 to 12 months aged animals only**, from three or four selected flocks, with earlier described population and species proportion ratios in the **provided sampling plan for each State/UT as such directly**. Thus, a maximum of **1080 secondary animal units to be collected for seromonitoring of the PPR in each State/UT of India by using an approved PPR C-ELISA kit**.

Note: In Sikkim State and Andaman and Nicobar Islands Union Territory: PPR Vaccination of small ruminants population, is not required to be implemented in these State / Union Territory.

Based on the seroprevalence study of PPR in small ruminants conducted at ICAR-NIVEDI during 2017-2018 cross-sectional survey (NIVEDI Annual Report 2018-2019-www.nivedi.res.in), in a unique niche of hilly terrain (Sikkim) and isolated islands (Andaman and Nicobar islands) settings, only a few samples from < 5 % epi-units (villages) have shown positive for PPRV antibodies with an overall seropositive of < 30% in the all surveyed epi-units with observed seroprevalence of <3 % in the state/UT. These studies imply that the PPR virus antibody has not yet become established in the small ruminants in Sikkim, and Andaman and Nicobar Islands (Balamurugan et al., 2019) despite the enzootic nature of the disease in the rest of India due to its unique geographical location. This necessitates the imposing of strict quarantine measures and restrictions in the small ruminants movements and trade along with the implementation of the intensive active surveillance programme to make a PPR free state/UT. Nevertheless, at the time of declaring India is provisionally free from PPR, further prevalence/surveillance study of PPR in the Sikkim also needs to be carried out as per Global Control and Eradication Strategy (GCES) sampling guidelines to support and demonstrate disease-free status in unvaccinated small ruminants in a unique hilly terrain north-eastern region of India.

As the country is going to adopt seromonitoring and serosurveillance of PPR at the national level in consonance with the GOI plan of PPR national control and eradication strategy 2025, it is recommended that sampling plan provided in this handbook to be endorsed by the OIE official before implementation as it is planned for the eradication of PPR from India.

Stratified Random Sampling - Bihar (Code - 5)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 500 + (Sheep + Goat) = 6939

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - Madhya Pradesh (Code - 19)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 500 + (Sheep + Goat) = 5559

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - Meghalaya (Code - 22)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 50 + (Sheep + Goat) = 2231

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - West Bengal (Code - 35)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 500 + (Sheep + Goat) = 9927

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - Chhattisgarh (Code - 7)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 200 + (Sheep + Goat) = 6122

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - Maharashtra (Code - 20)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 200 + (Sheep + Goat) = 16442

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - Manipur (Code - 21)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 30 + (Sheep + Goat) = 343

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - Telangana (Code - 31)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 500 + (Sheep + Goat) = 7565

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - Tripura (Code - 32)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 100 + (Sheep + Goat) = 993

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080

Stratified Random Sampling - West Bengal (Code - 35)

Species Selected for Stratification = Sheep + Goat

Number of Villages Having 500 + (Sheep + Goat) = 9927

Design Level Prevalence = 0.3

Cluster Level Prevalence = 0.03

Sensitivity of the test used = 0.92

Total No of Villages (Clusters) Selected = 108

Total No of Animals to be Sampled = 1080
